

Recombinant poxvirus expressing homologous genes inserted
into the poxviral genome

The present invention relates to a recombinant poxvirus
5 capable of expressing two or more homologous foreign genes.
Said genes are heterologous to the viral genome, but
homologous in comparison to each other. The genes are
especially derived from closely related variants or
subtypes of a microorganism. The invention further relates
10 to a method for preparing such recombinant poxvirus and to
the use of such recombinant poxvirus as medicament or
vaccine. Additionally, a method for affecting, preferably
inducing, an immune response in a living animal, including
a human, is provided.

15

Background of the invention

Every living organism is constantly challenged by
infectious or pathogenous agents such as bacteria, viruses,
fungi or parasites. The so-called immune system prevents
20 the organism from permanent infections, diseases or
intoxination caused by such agents.

The immune system of a mammal can be divided into a
specific and an unspecific part although both parts are
closely cross-linked. The unspecific immune response
25 enables an immediate defense against a wide variety of
pathogenic substances or infectious agents. The specific
immune response is raised after a lag phase, when the
organism is challenged with a substance for the first time.
This specific immune response is mainly based on the

production of antigen-specific antibodies and the generation of macrophages and lymphocytes, e.g. cytotoxic T-cells (CTL). The specific immune response is responsible for the fact that an individual who recovers from a specific infection is protected against this specific infection but still is susceptible for other infectious diseases. In general, a second infection with the same or a very similar infectious agent causes much milder symptoms or no symptoms at all. This so-called immunity persists for a long time, in some cases even lifelong. The underlying effect is often referred to as immunological memory, which can be used for vaccination proposes.

With the term vaccination a method is described, where an individual is challenged with a harmless, partial or inactivated form of the infectious agent to affect, preferably induce, an immunological response in said individual, which leads to long lasting - if not lifelong - immunity against the specific infectious agent.

The human smallpox disease is caused by Variola virus. Variola virus belongs to the family of *Poxviridae*, a large family of complex DNA viruses that replicate in the cytoplasm of vertebrate and invertebrate cells.

The family of *Poxviridae* can be divided into the two subfamilies *Chordopoxvirinae* and *Entomopoxvirinae* based on vertebrate and insect host range. The *Chordopoxvirinae* comprise beside others the genera of *Orthopoxviruses* and *Avipoxviruses* (Fields Virology, ed. by Fields B.N., Lippincott-Raven Publishers, 3rd edition 1996, ISBN: 0-7817-0253-4, Chapter 83).

The genera of *Orthopoxviruses* comprises variola virus, the causative agent of human smallpox, and also other viruses

with economical importance, e.g. camelpox, cowpox, sheeppox, goatpox, monkeypox and Vaccinia virus. All members of this genus are genetically related and have similar morphology or host range. Restriction endonuclease
5 maps have even shown high sequence identity from up to 90% between different members of the *Orthopoxviruses* (Mackett & Archard, [1979], J Gen Virol, 45: 683-701).

Vaccinia virus (VV) is the name given to the agent that was used at least the last 100 years for the vaccination
10 against smallpox. It is not known whether VV is a new species derived from cowpox or variola virus by prolonged serial passages, the living representative of a now extinct virus or maybe a product of genetic recombination. Additionally, in course of the VV history, many strains of
15 Vaccinia have arisen. These different strains demonstrate varying immunogenicity and are implicated to varying degrees with potential complications, the most serious of which is post-vaccinial encephalitis. However, many of these strains were used for the vaccination against
20 smallpox. For example the strains NYCBOH, Western Reserve or Wyeth were used primarily in US, while the strain Ankara, Bern, Copenhagen, Lister and MVA were used for vaccination in Europe. As a result of the worldwide vaccination program with these different strains of VV in
25 1980 the WHO finally declared the successful eradication of variola virus.

Today, VV is mainly used as a laboratory strain, but beside this it is still considered as the prototype of
30 *Orthopoxviruses*, which is also the reason why VV became one of the most intensively characterized viruses (Fields

Virology, ed. by Fields B.N., Lippincott-Raven Publishers, 3rd edition 1996, ISBN: 0-7817-0253-4, Chapter 83 and 84).

VV and more recently other poxviruses have been used for the insertion and expression of foreign genes. The basic technique for inserting foreign genes into live infectious poxvirus involves recombination between pox DNA sequences flanking a foreign genetic element in a donor plasmid and homologous sequences present in the rescuing poxvirus. Genetic recombination is, in general, the exchange of homologous sections of DNA between two strands of DNA. In certain viruses RNA may replace DNA. Homologous sections of nucleic acid are sections of nucleic acid (DNA or RNA), which have the same sequence of nucleotide bases. Genetic recombination may take place naturally during the replication or manufacture of new viral genomes within an infected host cell. Thus, genetic recombination between viral genes may occur during the viral replication cycle that takes place in a host cell, which is co-infected with two or more different viruses or other genetic constructs. A section of DNA from a first genome is used interchangeably in constructing the section of the genome of a second co-infecting virus in which the DNA is homologous with that of the first viral genome.

Successful expression of the inserted DNA genetic sequence by the modified infectious virus requires two conditions. First, the insertion should be into a nonessential region of the virus in order that the modified virus remains viable. The second condition for expression of inserted DNA is the presence of a promoter in the proper relationship to the inserted DNA. Regularly, the promoter is located upstream from the DNA sequence to be expressed.

The usefulness of recombinant VV expressing, e.g., Hepatitis B virus surface antigen (HBsAg), Influenza virus hemagglutinin (InfHA) or *Plasmodium knowlesi* sporozoite antigen, as live vaccines for the prophylaxis of infectious diseases has been demonstrated and reviewed (Smith, et al. [1984] Biotechnology and Genetic Engineering Reviews 2, 383-407).

A further advantage of VV is the capacity to take up multiple foreign sequences, genes or antigens within a single VV genome (Smith & Moss [1983], Gene, 25(1): 21-28). Furthermore, it has been reported that it is possible to elicit immunity to a number of heterologous infectious diseases with a single inoculation of a polyvalent vaccine (Perkus et al., [1985], Science, Vol. 229, 981-984).

One example of the expression of various antigens by a single VV is described by Bray et al. It was shown that a recombinant VV, which is capable to express three different structural proteins of Dengue virus serotype 4, namely the capsid (C), pre-membrane (prM), envelope (E) protein, and two non-structural proteins of Dengue virus serotype 4, namely NS1 and NS2a, had the ability to protect mice against a homologous Dengue virus serotype 4 challenge (Bray et al., [1989], Virology 2853-2856).

The Dengue virus with its four serotypes, Dengue virus serotype 1 (Den-1) through Dengue virus serotype 4 (Den-4), is one important member of the *Flavivirus* genus with respect to infections of humans. Dengue virus infection produces diseases that range from flu-like symptoms to severe or fatal illness, Dengue haemorrhagic fever (DHF) with shock syndrome (DSS). Dengue outbreaks continue to be a major public health problem in densely populated areas of

the tropical and subtropical regions, where mosquito vectors are abundant.

The concern over the spread of Dengue infection and other diseases induced by mosquito-borne Flaviviruses in many parts of the world has resulted in more efforts being made towards the development of Dengue vaccines, which could prevent both Dengue fever (DF), and Dengue haemorrhagic fever (DHF) and in vaccines useful to protect the vaccinated individual against infections induced by some or all mosquito-borne flaviviruses.

While most cases of DF are manifested after the first infection by any of the four serotypes, a large percentage of DHF cases occur in subjects who are infected for the second time by a serotype, which is different from the first infecting serotype of Dengue virus. These observations give rise to the hypothesis that sequential infection of an individual having antibodies against one Dengue serotype by a different virus serotype at an appropriate interval may result in DHF in a certain number of cases.

Accordingly, vaccination against one serotype does not result in a complete protection against Dengue virus infection, but only against infection with the same Dengue virus strain. Even more important, a person vaccinated against one serotype, has an increased risk of developing severe complications such as Dengue haemorrhagic fever when said person is infected from a Dengue virus strain of a different serotype.

Thus, a multivalent vaccine that contains antigens from all four Dengue virus serotypes is desired.

So far it had been suggested to prepare multivalent vaccines by mixing a panel of recombinant VV, each VV encoding sequences of a different viruses (Moss, [1990] Immunology, 2, 317-327). However, such a multivalent vaccine comprises several disadvantages. Firstly, it is cumbersome to generate several independent recombinant VV. Beside the separated production processes, also quality control and quality assurance is highly time consuming. Secondly, an infection with a mixture of recombinant viruses expressing different sequences always bears the risk that the infection event is not particularly well balanced. The main risk is that only individual recombinants, but not all different recombinants comprised in the multivalent vaccine will infect target cells. One reason might be an uneven distribution of recombinant viruses. Another reason might be interferences between the different recombinant viruses while infecting single cells. Such interferences are known as phenomenon of superinfection. In this case, only some antigens, but not all different antigens of the multivalent vaccine will finally be expressed from infected cells and, thus, presented to the immune system of a patient. As a consequence, immune protection will be obtained only against some of the antigens, but is far from providing a complete immune protection against the various antigens presented or presentable by the multivalent vaccine.

In the context of a vaccine against Dengue virus infection the approach of a multivalent vaccine has the disadvantage that if the different sequences are expressed in different amounts or in an unpredictable manner, as it had been shown for the envelope protein of Dengue virus 2 (Deuble et al.,

[1988], J. Virol 65: 2853), then such a vaccination is highly risky for a patient. An incomplete vaccination using a panel of recombinant Vaccinia viruses will only provide an immune protection against some, but not against all serotypes of Dengue virus. Unfortunately, in case of Dengue infection an incomplete vaccination is extremely unacceptable, since it increases the risk of lethal complications such as Dengue hemorrhagic fever.

Object of the Invention

It is, therefore, an object of the present invention to provide a stable, effective and reliable vaccine against infectious diseases, which can be caused by more than one strain, clade, variant, subtype or serotype of said infectious disease causing microorganism.

It is a further object of the present invention to provide a stable, effective and reliable vaccine against Dengue virus infections, which allows reliable vaccination against all Dengue virus serotypes.

Detailed description of the Invention

The present invention is based on the idea to include into a poxvirus homologous genes derived from different strains, clades, variants, subtypes or serotypes of an infectious disease causing microorganism. As already mentioned above, there are, for example, 4 groups, subtypes or serotypes of Dengue virus existing which are all comprising the same types of genes as, e.g., the gene encoding the capsid (C) protein, the gene encoding the pre-membrane (PrM) or

envelope (E) protein. However, the nucleic acid sequence of the same type of gene is not completely identical and not perfectly homologous, respectively, in all 4 serotypes: For example, sequence comparison (with Lasergene 4.05 Magalign, 5 Macintosh) between the PrM genes of Dengue virus serotype 1, 2, 3 and 4 (PrM1-4) revealed a sequence identity of 66.5-72.9%, i.e., a homology of appr. 65-75%. It is assumed that differences and variations, respectively, in the genes of different subtypes of infectious disease causing 10 microorganisms are the reasons why vaccination against one subtype does not automatically result in protection against infections with other variants of the same microorganism. It was, therefore, the idea to generate a recombinant virus including closely related or homologous genes derived from 15 different strains, clades, variants, subtypes or serotypes of an infectious disease causing microorganism. However, as also already indicated above, homologous recombination between homologous sequences occur during the viral life cycle and even takes place between sections of DNA that are 20 not perfectly homologous. It was, thus, expected that the insertion of homologous genes in a single viral genome would result in homologous recombination and, thus, in deletions of the inserted homologous genes.

However, when generating a recombinant poxvirus comprising 25 in its genome at least two foreign genes with a homology of at least 60%, it was unexpectedly found that said homologous genes remain stably inserted into the viral genome.

Even if homologous genes, preferably with a homology of at 30 least 50%, are inserted into different insertion sites of the viral genome, the genes also remain stably inserted

into the viral genome: In this case, it was expected that recombination events between said homologous genes would additionally result in loss of viral genes important for amplification of the virus and for the viral life cycle, respectively, i.e., it was expected that the viral life cycle would seriously be damaged. Since, additionally, the frequency of recombination is proportional to the distance between two linked genes, it was expected that frequency of recombination events between two or more homologous genes located in different insertion sites would be high and, thus, result in deletions of said genes and/or in severe interferences. Accordingly, it was extremely surprising that no recombination events occurred, but that the homologous genes remained stably inserted into the different insertion sites of the viral genome.

According to the prior art, a recombinant poxvirus containing foreign DNA from flavivirus, such as Japanese Encephalitis Virus (JEV), Yellow Fever Virus (YFV) and Dengue Virus, are known (US Patent No. 5,514,375). However, each gene derived from said flaviviruses were inserted only a single time and into the same insertion site. Additionally, sequence comparison with a suitable computer software (Lasergene 4.05 Megalign, Macintosh) revealed a homology of the genes inserted into the poxviral genome and derived from JEV of 20.2%-29.6%, from YFV of 29.2%-45.3%, and from Dengue Virus of 22.8%-29.5%.

Similar disclosure applies to WO 98/13500 describing insertion of Dengue virus antigens into the same insertion site of Modified Vaccinia Virus Ankara (MVA), especially into deletion site II.

US Patent No. 5,338,683 describes insertion of gp 13 and 14 of herpesvirus glycoprotein genes into two different insertion sites of a single recombinant poxvirus; however, both genes have a homology of 25.2% only.

- 5 Sequence comparison between influenza virus haemagglutinin and nucleoprotein gene inserted into the same insertion site (deletion site III) of a Modified Vaccinia Virus Ankara (MVA) resulted in a homology of 49.1% (US Patent No. 5,676,950; Sutter *et al.*, [1994], Vaccine 12: 1032).
- 10 US Patent No. 5,891,442 discloses a recombinant poxvirus containing the coding sequence for the polyprotein VP2, VP3 and VP4 of infectious bursal disease. Said genes were fused and, thus, inserted into a single insertion site and have a homology of 41.9%-50.3%.
- 15 Finally, US Patent No. 6,217,882 describes a recombinant swinepox virus vector containing pseudorabies antigens gp50 and gp63 with a homology of 52.7% inserted into the same insertion site.

In summary, it can be stated that according to the prior
20 art homologous genes or sequences having a homology of at least 50% are all inserted into the same or a single insertion site within the viral genome.

According to the present invention, homologous genes or sequences have a homology of at least 50%, i.e., a homology
25 of 50% - 100%, i.e., at least 50% identical nucleotide bases. Genes or sequences having a homology below 50% can be considered as being heterologous. In the context of the present invention, the term "homologous" or "homology" is used when genes or sequences are compared to each other,
30 whereas the terms "foreign" gene, "exogenous" or

"heterologous" sequence are used when genes or sequences are compared to the poxviral genome; i.e., said terms refer to a DNA sequence which is in nature not normally found associated with a poxvirus as used according to the invention. Accordingly, the present invention relates to a recombinant poxvirus comprising at least two genes which are heterologous in comparison to the viral genome, but which are homologous among each other. The term "genes" refers to coding sequences, which encode, e.g., proteins, polypeptides, peptides, antigens and the like. Proteins, polypeptides or peptides translated from homologous genes fulfill the same tasks and show the same functional properties. Homologous genes are regularly derived from different, but related sources or organisms. According to one embodiment of the present invention, the homology in the coding sequences is preferably 70% to 80%, more preferably 80% to 90% or 90% to 100%. Most preferred is a homology of 65% to 75%.

Since the recombinant poxvirus according to the present invention comprises the relevant genetic information in one single infectious unit or in one virus particle only, there is no risk of uneven infection and unbalanced expression of the different homologous sequences. Thus, the recombinant poxvirus according to the present invention comprising and capable of expressing several closely or even closest related genes or almost identical sequences in one infected cell is particularly advantageous for the generation of multivalent vaccines.

This advantage is particularly interesting for the development of vaccines against diseases, which can be caused by several closely related strains or serotypes of a

virus, like e.g. Dengue virus. Recombinant poxviruses comprising homologous genes of different Dengue virus serotypes are described in the Examples.

5 The homologous genes or sequences according to the present invention can be derived from any microorganism, such as any virus except the vector virus, any bacterium, any fungus or parasite. Preferably, the homologous genes or sequences are derived from an infectious or pathogenic microorganism and most preferably from different strains or
10 clades, variants, subtypes or serotypes of said microorganism.

The terms "strain" or "clade" are technical terms, well known to the practitioner, referring to the taxonomy of microorganisms. The taxonomic system classifies all so far
15 characterised microorganisms into the hierarchic order of *Families, Genera, species, strains* (Fields Virology, ed. by Fields B.N., Lippincott-Raven Publishers, 4th edition 2001). While the criteria for the members of *Family* is their phylogenetic relationship, a *Genera* comprises all
20 members which share common characteristics, and a *species* is defined as a polythetic class that constitutes a replicating lineage and occupies a particular ecological niche. The term "strain" or "clade" describes a microorganism, i.e. virus, which shares the common
25 characteristics, like basic morphology or genome structure and organisation, but varies in biological properties, like host range, tissue tropism, geographic distribution, attenuation or pathogenicity. The term "variants" or "serotypes" further distinguishes between members of the
30 same strain, also called subtypes, which show individual

infection spectra or antigenic properties due to minor genomic variations.

According to a further embodiment of the present invention the homologous genes or sequences are selected from
5 viruses, preferably viruses, which belong to the genera of Flaviviruses, such as preferable - but not limited to - Dengue virus, West Nile virus or Japanese encephalitis virus; which belong to the genera of Retroviruses, such as preferable - but not limited to - Human Immunodeficiency
10 Virus (HIV); which belong to the genera of Enteroviruses, such as preferable - but not limited to - Hand, Foot and Mouth disease, EV71; which belong to the genera of Rotaviruses or which belong to the genera of Orthomyxoviruses, such as preferable - but not limited to -
15 Influenza virus. Most preferred are homologous genes derived from a Flavivirus.

According to a further preferred embodiment, the homologous genes are selected from Dengue virus genes, preferably C, NS1 and/or NS2, or preferably E, more preferably PrM. Most
20 preferred are homologous genes derived from different serotypes of the virus, wherein said genes may be derived from one, two, three or from all of the 4 Dengue virus serotypes.

According to still a further embodiment the homologous
25 genes are selected from different HIV stains or clades. Preferably the homologous genes are selected from the gag/pol coding sequence, more preferably from the env coding sequence or further preferably from a combination of structural and/or regulatory HIV coding sequences.

30 The vector virus suitable for the present invention is selected from the group of poxviruses, which can be easily

cultured in selected host cells as, e.g., avian host cells, but which are highly replication deficient or actually not replicating in humans or human cells.

According to some preferred embodiments the poxvirus
5 according to the present invention is selected from the group comprising canarypox viruses (Plotkin et al. [1995] Dev Biol Stand. vol 84: pp 165-170. Taylor et al. [1995] Vaccine, Vol 13. No. 6: pp 539-549), fowlpox viruses (Afonso et al. [2000] J Virol, pp 3815-3831. Fields
10 Virology, ed. by Fields B.N., Lippincott-Raven Publishers, 4th edition 2001, Chapter 85: page 2916), penguin pox viruses (Stannard et al. [1998] J Gen Virol, 79, pp 1637-1649) or derivatives thereof. Since these viruses belong to the genera of Avipoxviruses they can be easily cultured and
15 amplified in avian cells. However, in mammalian or human cells they are replication defective, which means that essentially no or nearly no infectious progeny viruses are produced.

According to a further embodiment of the present invention
20 a Vaccinia viruse, preferably an attenuated Vaccinia virus, is used for the generation of recombinant poxviruses comprising two or more homologous genes.

Although it is known that Vaccinia viruses (VV) may undergo homologous recombination of short homologous sequences and
25 thereby may delete homologous sequences (Howley et al., [1996], Gene 172: 233-237) the inventors provide a recombinant Vaccinia virus including homologous sequences or genes stably inserted into its genome. This finding is particularly unexpected, since according to Howely et al.
30 already short sequences from up to 300 base pairs (bp) were sufficient to induce genomic rearrangement and deletion of

homologous sequences in Vaccinia virus. The practitioner would, thus, expect that longer sequences would induce recombination events with an even higher probability. However, according to the present invention even sequences
5 comprising complete homologous genes can be stably inserted into the genome of Vaccinia virus.

One - not limiting - example of a vaccinia virus is the highly attenuated and host range restricted Vaccinia strain, Modified Vaccinia Ankara (MVA) (Sutter, G. et al.
10 [1994], Vaccine 12: 1032-40). MVA has been generated by about 570 serial passages on chicken embryo fibroblasts of the Ankara strain of Vaccinia virus (CVA) (for review see Mayr, A., et al. [1975], Infection 3, 6-14). As a consequence of these long-term passages CVA deleted about
15 31 kilobases of its genomic sequence. The resulting virus strain, MVA, was described as highly host cell restricted (Meyer, H. et al., J. Gen. Virol. 72, 1031-1038 [1991]). A typical MVA strain is MVA 575 that has been deposited at the European Collection of Animal Cell Cultures under the
20 deposition number ECACC V00120707.

In another embodiment the MVA-Vero strain or a derivative thereof can be used according to the present invention. The strain MVA-Vero has been deposited at the European Collection of Animal Cell Cultures under the deposition
25 number ECACC V99101431 and ECACC 01021411. The safety of the MVA-Vero is reflected by biological, chemical and physical characteristics as described in the International Patent Application PCT/EP01/02703. In comparison to normal MVA, MVA-Vero has one additional genomic deletion.

30 The term "derivatives" of a virus according to the present invention refers to progeny viruses showing the same

characteristic features as the parent virus but showing differences in one or more parts of its genome.

Still another embodiment according to the present invention uses MVA-BN. MVA-BN has been deposited at the European
5 Collection of Animal Cell Cultures with the deposition number ECACC V00083008. By using MVA-BN or a derivative thereof a particular safe virus vaccine is generated, since it has been shown that the MVA-BN virus is an extremely high attenuated virus, derived from Modified Vaccinia
10 Ankara virus. Therefore, in the most preferred embodiment, MVA-BN or derivatives thereof containing two or more homologous genes according to the present invention is used as viral vector. The term "derivative of MVA-BN" describes a virus, which has the same functional characteristics
15 compared to MVA-BN. The features of MVA-BN, the description of biological assays allowing the evaluation whether an MVA is MVA-BN and a derivative thereof and methods allowing the generation of MVA-BN or derivatives thereof are described in WO 02/42480 (incorporated herein by reference). One easy
20 way to examine a functional characteristic of MVA-BN or derivatives thereof is its attenuation and lack of replication in human HaCat cells.

In a recombinant poxvirus according to the present invention the expression of the exogenous sequences is
25 controlled preferably by a poxviral transcriptional control element, more preferably by an MVA, canary pox, fowl pox, or penguin pox transcriptional control element or most preferably a Vaccinia virus promoter. Poxviral transcriptional control elements according to the present
30 invention comprise furthermore every transcriptional control element functional in a poxviral system.

The insertion of the exogenous sequences according to the present invention is preferably directed into a non-essential region of the virus genome. Non-essential regions are e.g. loci or open reading frames (ORF) of poxviral genes, which are non-essential for the poxviral life cycle. Also intergenic regions, which describe the space inbetween two ORF, are considered as non-essential regions according to the present invention. In another embodiment of the invention, the exogenous sequences are inserted at a naturally occurring deletion site of the MVA genome (disclosed in PCT/EP96/02926 and incorporated herein by reference).

The orientation of the inserted DNA does not have an influence on the functionality or stability of the recombinant virus according the present invention.

Since the recombinant poxvirus according to the invention is highly growth restricted and, thus, highly attenuated, it is an ideal candidate for the treatment of a wide range of mammals including humans and even immune-compromised humans. Hence, the present invention also provides a pharmaceutical composition and also a vaccine for inducing an immune response in a living animal body, including a human.

The pharmaceutical composition may generally include one or more pharmaceutically acceptable and/or approved carriers, additives, antibiotics, preservatives, adjuvants, diluents and/or stabilizers. Such auxiliary substances can be water, saline, glycerol, ethanol, wetting or emulsifying agents, pH buffering substances, or the like. Suitable carriers are typically large, slowly metabolized molecules such as proteins, polysaccharides, polylactic acids, polyglycollic

acids, polymeric amino acids, amino acid copolymers, lipid aggregates, or the like.

For the preparation of vaccines, the recombinant poxvirus according to the invention is converted into a physiologically acceptable form. This can be done based on the experience in the preparation of poxvirus vaccines used for vaccination against smallpox (as described by Stickl, H. et al. [1974] Dtsch. med. Wschr. 99, 2386-2392). For example, the purified virus is stored at -80°C with a titre of 5×10^8 TCID₅₀/ml formulated in about 10mM Tris, 140 mM NaCl pH 7.4. For the preparation of vaccine shots, e.g., 10^2 - 10^8 particles of the virus are lyophilized in 100 ml of phosphate-buffered saline (PBS) in the presence of 2% peptone and 1% human albumin in an ampoule, preferably a glass ampoule. Alternatively, the vaccine shots can be produced by stepwise freeze-drying of the virus in a formulation. This formulation can contain additional additives such as mannitol, dextran, sugar, glycine, lactose or polyvinylpyrrolidone or other aids such as antioxidants or inert gas, stabilizers or recombinant proteins (e.g. human serum albumin) suitable for *in vivo* administration. The glass ampoule is then sealed and can be stored between 4°C and room temperature for several months. However, as long as no need exists the ampoule is stored preferably at temperatures below -20°C .

For vaccination or therapy the lyophilisate can be dissolved in 0.1 to 0.5 ml of an aqueous solution, preferably physiological saline or Tris buffer, and administered either systemically or locally, i.e. parenteral, subcutaneous, intravenous, intramuscular, by scarification or any other path of administration known to

the skilled practitioner. The mode of administration, the dose and the number of administrations can be optimized by those skilled in the art in a known manner. However, most commonly a patient is vaccinated with a second shot about
5 one month to six weeks after the first vaccination shot.

The recombinant virus according to the present invention is used for the introduction of the exogenous coding sequences into a target cell. The introduction of an exogenous coding sequence into a target cell may be used to produce *in vitro*
10 proteins, polypeptides, peptides, antigens and epitopes, respectively. Furthermore, the method for introduction of a homologous or of a heterologous sequence into cells may be applied for *in vitro* and *in vivo* therapy. For *in vitro* therapy, isolated cells that have been previously (*ex vivo*)
15 infected with the recombinant poxvirus according to the invention are administered to the living animal body for inducing an immune response. For *in vivo* therapy, the recombinant poxvirus according to the invention is directly administered to the living animal body for inducing an
20 immune response. In this case, the cells surrounding the site of inoculation are directly infected *in vivo* by the virus or its recombinant according to the invention. After infection, the cells synthesize the proteins, polypeptides, peptides or antigens, which are encoded in the exogenous
25 coding sequences and, subsequently, present them or parts thereof on the cellular surface. Specialized cells of the immune system recognize the presentation of such foreign proteins, polypeptides, peptides, antigens and epitopes and launch a specific immune response.

30 Methods to obtain recombinant poxviruses or to insert exogenous coding sequences into a poxviral genome are well

known to the person skilled in the art. Additionally, the method is described in the examples and can also be deduced or completed from the following references:

- 20

For the generation of recombinant poxviruses according to the present invention different methods may be applicable: The DNA sequence to be inserted into the virus may be placed into an *E. coli* plasmid construct into which DNA homologous to a section of DNA of the poxvirus has been inserted. Separately, the DNA sequence to be inserted is ligated to a promoter. The promoter-gene linkage is positioned in the plasmid construct so that the promoter-gene linkage is flanked on both ends by DNA homologous to a DNA sequence flanking a region of pox DNA containing a non-

25

30

essential locus. The resulting plasmid construct is amplified by growth within *E. coli* bacteria and isolated. The isolated plasmid containing the DNA gene sequence to be inserted is transfected into a cell culture, e.g., chicken
5 embryo fibroblasts (CEFs), along with the poxvirus. Recombination between homologous pox DNA in the plasmid and the viral genome, respectively, gives a poxvirus modified by the presence of foreign DNA sequences.

According to a more preferred embodiment, a cell of a
10 suitable cell culture as, e.g., CEF cells, is infected with a poxvirus. The infected cell is, subsequently, transfected with a first plasmid vector comprising the foreign gene, preferably under the transcriptional control of a poxvirus expression control element. As explained above, the plasmid
15 vector also comprises sequences capable of directing the insertion of the exogenous sequence into a selected part of the poxviral genome. Optionally, the plasmid vector contains also a cassette comprising a marker and/or selection gene operably linked to a poxviral promoter.
20 Suitable marker or selection genes are, e.g., the genes encoding the Green Fluorescent Protein, β -Galactosidase, neomycin, phosphoribosyltransferase or other markers. The use of selection or marker cassettes simplifies the identification and isolation of the generated recombinant
25 poxvirus. However, a recombinant poxvirus can also be identified by PCR technology. Subsequently, a further cell is infected with the recombinant poxvirus obtained as described above and transfected with a second vector comprising a gene, which is homologous to the gene included
30 in the first vector. In case, this gene shall be included into a different insertion site of the poxviral genome, the

second vector also differs in the sequence directing the integration of the homologous gene into the genome of the poxvirus. After homologous recombination occurred, the recombinant virus comprising two homologous genes can be isolated. For introducing more than two homologous genes into the recombinant virus, the steps of infection and transfection are repeated by using the recombinant virus isolated in previous steps for infection and by using a further vector comprising a further homologous gene for transfection.

Alternatively, the steps of infection and transfection as described above are interchangeable, i.e., a suitable cell may at first be transfected by the plasmid vector comprising the foreign gene and, then, infected with the poxvirus.

As a further alternative, it is also possible to introduce each homologous gene into different viruses, coinfect a cell with all the obtained recombinant viruses and screen for a recombinant including all homologous genes.

The invention further provides a kit comprising two or more plasmid vector constructs capable of directing the integration of expressable, homologous genes into the poxvirus genome. Beside a suitable cloning site such plasmid vectors comprise sequences capable of directing the insertion of the exogenous sequence to selected parts in the poxviral genome. Optionally, such vectors comprise selection or marker gene cassettes. The kit further comprises means and instructions to select viruses, which are recombinant for one or several of the homologous genes and optionally a selection or marker gene, inserted via said vector constructs.

According to another further embodiment the invention includes DNA sequences or parts thereof derived from or homologous to the recombinant poxvirus of the present invention. Such sequences comprise at least part of the
5 exogenous sequence comprising at least a fragment of one of the homologous gene according to the present invention and at least a fragment of the genomic poxvirus sequence according to the present invention, said genomic poxvirus sequences preferably flanking the exogenous sequence.

10 Such DNA sequences can be used to identify or isolate the virus or its derivatives, e.g. by using them to generate PCR-primers, hybridization probes or in array technologies.

Short Description of the Figures

15 **Figure 1:** Schematic presentation of the insertion sites of the four PrM (= pre-membrane) genes (serotype 1-4) in the MVA genome according to Example 1.

The following examples will further illustrate the present
5 invention. It will be well understood by a person skilled
in the art that the provided examples in no way may be
interpreted in a way that limits the applicability of the
technology provided by the present invention to this
examples.

Example 1**Insertion vectors***Insertion vector for deletion A*

For the insertion of exogenous sequences into the MVA
5 genome at the so-called deletion A or deletion 1
respectively, corresponding to the genome position 7608-
7609, a plasmid vector was constructed, which comprises
about 600 bp of the flanking sequences adjacent to the
deletion site A. To isolate the flanking sequences from the
10 genomic MVA-BN DNA, suitable PCR primers can be designed
with suitable computer software (DNAsis, Hitachi software
engineering, San Bruno, USA). Such primers comprise
extensions with restriction enzyme sites, which will be
used to clone the flanking sequences into a vector plasmid.
15 In between these flanking sequences, a selection gene
cassette is introduced, e.g a NPT II gene (neomycin
resistance) under the transcriptional control of a poxviral
promoter. Additionally, there is a cloning site for the
insertion of additional genes or exogenous sequences to be
20 inserted into deletion site A. One such vector construct
according to the present invention is disclosed in Figure 2
(pBNX10).

Insertion vector for deletion E

For the insertion of exogenous sequences into the MVA
25 genome at the so-called deletion E or deletion 4,
respectively, corresponding with the genome position
170480-170481, a vector was constructed, which comprises
about 600 bp of the flanking sequences adjacent to the

deletion site E. The vector is designed and constructed like described above. In between the flanking sequences is located an EGFP gene (green fluorescence protein, Clonetech) under the transcriptional control of a poxviral promoter. Additionally, there is a cloning site for the insertion of additional genes or sequences to be inserted into deletion site A. One such vector construct according to the present invention is disclosed in Figure 3 (pBNX32).

Insertion vector for deletion 2

For the insertion of exogenous sequences into the MVA genome at the so-called deletion 2, corresponding with the genome position 20718-20719, a vector was constructed, which comprises about 600 bp of the flanking sequences adjacent to the deletion site 2. The vector is designed and constructed like described above. In between the flanking sequences is located an hbfp gene (humanized blue fluorescing protein, Pavalkis GN et al.) under the transcriptional control of a poxviral promoter. Additionally, there is a cloning site for the insertion of additional genes or sequences to be inserted into deletion site 2. One such vector construct according to the present invention is disclosed in Figure 4 (pBNX36).

Insertion vector for intergenetic region, I4L

For the insertion of exogenous sequences in the intergenetic region, between the ORF I3L and I4L, corresponding to the genome position 56760, a vector was constructed, which comprises about 600 bp of the flanking sequences adjacent to the intergenetic region at the I4L locus. The vector is designed and constructed like described above. In between the flanking sequences is

located an *Ecogpt* gene (or *gpt* stands for phosphoribosyl-transferase gene isolated from *E.coli*) under the transcriptional control of a poxviral promoter. Additionally, there is a cloning site for the insertion of
5 additional genes or sequences to be inserted into the intergenetic region after the I4L ORF. One such vector construct according to the present invention is disclosed in Figure 5 (pBNX39).

**Construction of recombinant poxvirus comprising several
10 homologous genes integrated in its genome.**

Insertion vectors

For the insertion of the four PrM genes of the four serotypes of Dengue virus in the MVA genome four independent recombination vectors were used.

15 These vectors contain - as described in details above - sequences homologous to the MVA genome for targeting insertion by homologous recombination. Additionally each vector contains a selection- or reporter gene cassette.

The PrM sequences of the four Dengue virus serotypes were
20 synthetically made by oligo annealing and PCR amplification. The PrM sequences were cloned downstream of poxvirus promoter elements to form an expression cassette. This expression cassette was, then, cloned into the cloning site of the relevant insertion vector constructs.

25 As result, the insertion vector construct for deletion A contained the PrM gene of Dengue virus serotype 2 (Figure 6 - pBN39). The insertion vector construct for deletion 2 contained the PrM gene of Dengue virus serotype 1 (Figure 7 - pBN49). The insertion vector construct for intergenic

region I4L contained the PrM gene of Dengue virus serotype 3 (Figure 8 - pBN50). The insertion vector construct for deletion E contained the PrM gene of Dengue virus serotype 4 (Figure 9 - pBN40).

5 *PCR verification of the insertion vectors*

For verification of the cloning strategies, PCR assays were performed. For these PCR assays the selected primer pairs are a combination of a primer specifically binding to the specific flanking sequence relative to the insertion site
10 and a second primer specifically binding to one of the highly homologous Dengue virus PrM genes.

The insertion vector for deletion A containing the PrM gene of Dengue virus serotype 2 was screened with the Primers oBN93 (CGCGGATCCATGCTGAACATCTTGAACAGGAGACGCAGA. SEQ ID NO.:
15 1) and oBN477 (CATGATAAGAGATTGTATCAG. SEQ ID NO.: 2).

The insertion vector for deletion 2 containing the PrM gene of Dengue virus serotype 1 was screened with the Primers oBN194
(ATGTTGAACATAATGAACAGGAGGAAAAGATCTGTGACCATGCTCCTCATGCTGCTGC
20 CCACAGCCCTGGCGTTCCATCT. SEQ ID NO.: 3) and oBN476
(GATTTTGCTATTTCAGTGGACTGGATG. SEQ ID NO.: 4).

The insertion vector for intergenic region I4L containing the PrM gene of Dengue virus serotype 3 was screened with the
Primers oBN255
25 (CCTTAATCGAATTCTCATGTCATGGATGGGGTAACCAGCATTAATAGT. SEQ ID NO.: 5) and oBN479 (GCTCCCATTC AATTCACATTGG. SEQ ID NO.: 6).

The insertion vector for deletion E containing the PrM gene of Dengue virus serotype 4 was screened with the Primers oBN210
30 (ATCCCATTCCTGAATGTGGTGTAAAGCTACTGAGCGCTTCTCTCGTCTCCGTTCTCC

GCTCTGGGTGCATGTCCCATAC. SEQ ID NO.: 7) and oBN478
(GTACATGGATGATATAGATATG. SEQ ID NO.: 8).

PCR experiments are performed in a Thermal cycler GeneAmp
9700 (Perkin Elmer) using the Taq DNA Polymerase Kit
5 containing 10x PCR buffer, MgCl₂ buffer and Taq DNA
polymerase (Roche, Cat.no. 201205) or equivalent. In
general the PCR reactions were prepared with a total
reaction volume of 50 µl containing 45 µl mastermix, the
sample DNA and ddH₂O as required. The mastermix should be
10 prepared with 30.75 µl DdH₂O, 5 µl 10x buffer, 1 µl dNTP-
mix (10 mM each), 2.5 µl of each primer (5 pmol/µl), 3 µl
MgCl₂ (25 mM) and 0.25 µl Taq-polymerase (5 U/µl).

The amplification was performed using the following
15 programme:

1)	Denaturation:	4 min	94°C
2)	30 Cycles:		
	Denaturation:	30 sec	94°C
20	Annealing:	30 sec	55°C
	Elongation:	1-3 min	72°C
3)	Elongation	7 min	72°C
4)	Store		4°C

25 Based on the size of the inserted gene the elongation time
should at least be 1min/kb.

The PCR results shown in Figure 10 demonstrate the
specificity of the primer combinations used for the single
insertions.

30 The primer combination oBN194/oBN476 is specific for
deletion 2 and PrM1 as insert. The expected PCR fragment of

plasmid pBN49 has a size of 678 bp (shown in lane 3, upper part of the gel).

The primer combination oBN255/oBN479 is specific for intergenic region I4L and PrM3 as insert. The expected PCR
5 fragment of plasmid pBN50 has a size of 825 bp (shown in lane 9, upper part of the gel).

The primer combination oBN210/oBN478 is specific for deletion E and PrM4 as insert. The expected PCR fragment of plasmid pBN40 has a size of 607 bp (shown in lane 5, lower
10 part of the gel).

The primer combination oBN93/oBN477 is specific for deletion A and PrM2 as insert. The expected PCR fragment of plasmid pBN39 has a size of 636 bp (shown in lane 11, lower part of the gel).

15 *Generation of the recombinant MVA via homologous recombination*

For expression of foreign genes by a recombinant MVA, these genes have to be inserted into the viral genome by a process called homologous recombination. For that purpose,
20 the foreign gene of interest had been cloned into an insertion vector, as described above. This vector has to be transfected after infection of cells with MVA-BN. The recombination will take place in the cellular cytoplasm of the infected and transfected cells. With help of the
25 selection and/or reporter cassette, which is also contained in the insertion vector, cells comprising recombinant viruses are identified and isolated.

Homologous recombination

For homologous recombination, BHK (Baby hamster kidney) cells or CEF (primary chicken embryo fibroblasts) cells are seeded in 6 well plates using DMEM (Dulbecco's Modified
5 Eagles Medium, Gibco BRL) + 10% fetal calf serum (FCS) or VP-SFM (Gibco BRL) + 4mmol/l L-Glutamine for a serum free production process.

Cells need to be still in the growing phase and, therefore, should reach 60-80% confluence on the day of transfection.
10 Cells were counted before seeding, as the number of cells has to be known for determination of the multiplicity of infection (moi) for infection.

For infection, the MVA stock is diluted in DMEM/FCS or VP-SFM/L-Glutamine so that 500 μ l dilution contain an
15 appropriate amount of virus that will give a moi of 0.01. Cells are assumed to be divided once after seeding. The medium is removed from cells and cells are infected with 500 μ l of diluted virus for 1 hour rocking at room temperature. The inoculum is removed and cells are washed
20 with DMEM/VP-SFM. Infected cells are left in 1.6ml DMEM/FCS and VP-SFM/L- Glutamine respectively while setting up transfection reaction (Qiagen Effectene Kit).

For transfection, the "Effectene" transfection kit (Qiagen) is used. A transfection mix is prepared of 1-5 μ g of
25 linearized insertion vector (total amount for multiple transfection) with buffer EC to give a final volume of 150 μ l. Add 8.0 μ l Enhancer per μ g DNA, vortex and incubate at room temperature for 5 min. Then, 25 μ l of Effectene are added per μ g DNA after vortexing stock tube and the
30 solution is mixed thoroughly by vortexing and incubated at room temperature for 10 min. 600 μ l of DMEM/FCS and VP-

SFM/L-Glutamine respectively, are added, mixed and subsequently, the whole transfection mix is added to the cells, which are already covered with medium. Gently the dish is rocked to mix the transfection reaction. Incubation
5 takes place at 37°C with 5%CO₂ over night. The next day the medium is removed and replaced with fresh DMEM/FCS or VP-SFM/L-Glutamine. Incubation is continued until day 3.

For harvesting, the cells are scraped into medium, then the cell suspension is transferred to an adequate tube and
10 frozen at -20°C for short-term storage or at -80°C for long term storage.

Insertion of PrM4 into MVA

In a first round, cells were infected with MVA-BN according to the above-described protocol and were additionally
15 transfected with insertion vector pBN40 containing the PrM gene of Dengue virus serotype 4 and as reporter gene the EGFP gene. Since the transfected vector contains a reporter gene, EGFP, the synthesized protein is detectable latest on day three in cells infected with a recombinant virus.
20 Resulting recombinant viruses have to be purified by plaque purification.

For plaque purification infected cells (fluorescing or stained) are isolated with a pipet tip, resuspended and aspirated in 200µl PBS or medium. Then a fresh culture dish
25 containing about 10E6 cells is infected with 100µl of the resuspended plaques. After 48h cells are taken up in 300µl PBS. DNA is extracted from suspension and screened with PCR analysis. A clone that shows the expected bands is chosen and fresh 6-well plates are infected with different amounts
30 of this virus. Overlaying the wells with 1% agarose avoids

further spreading of virus. After 48h infected cells comprising a recombinant virus clone are isolated.

This procedure is repeated until no wild-type MVA-BN can be detected in the PCR analysis.

- 5 After 4 rounds of plaque purification recombinant viruses, MVA-PrM4, were identified by PCR assays using a primer pair selectively amplifying the expected insertion (oBN210 and oBN478, as described above) and as control a primer pair specifically recognizing the insertion site deletion E
10 (oBN453: GTTGAAGGATTCACTTCCGTGGA, SEQ ID NO.: 9 and oBN454: GCATTCACAGATTCTATTGTGAGTC, SEQ ID NO.: 10)

Insertion of PrM2 into MVA-PrM4

Cells were infected with MVA-PrM4 according to the above described protocol and were additionally transfected with
15 insertion vector pBN39 containing the PrM gene of Dengue virus serotype 2 and as selection gene the NPT II, a neomycin resistance gene. For purification of recombinant MVA expressing an antibiotic resistance gene three rounds of virus amplification under selective conditions before
20 plaque purification are recommended. For neomycinphosphotransferase selection G418 is added to the medium. G418 is a derivative of neomycin and inhibits the protein-biosynthesis by interference with the action of the ribosomes. NPT gene activity inactivates G418 by
25 phosphorylation.

After 16 rounds of plaque purification under neomycin selection recombinant viruses, MVA-PrM4/PrM2, were identified by PCR assays using a primer pair selectively amplifying the expected insertion (oBN93 and oBN477, as
30 described above) and as control a primer pair specifically

recognizing the insertion site deletion A (oBN477: as described above) and oBN452: GTTTCATCAGAAATGACTCCATGAAA, SEQ ID NO.: 11). Additionally also insertion of PrM4 into deletion E is verified with the primer pairs: oBN210 -
5 oBN478 and oBN453 - oBN454.

Insertion of PrM1 into MVA

In a first round, cells were infected with MVA-BN according to the above described protocol and were additionally transfected with insertion vector pBN49 containing the PrM
10 gene of Dengue virus serotype 1 and as reporter gene the hbfp, the gene for humanized blue fluorescing protein. The synthesized hbfp protein is detectable on day three in cells infected with a recombinant virus. Resulting recombinant viruses were purified by plaque purification.

15 After 10 rounds of plaque purification recombinant viruses, MVA-PrM1, were identified by PCR assays using a primer pair selectively amplifying the expected insertion (oBN194 and oBN476, as described above) and as control a primer pair specifically recognizing the insertion site deletion 2
20 (oBN54: CGGGGTACCCGACGAACAAGGAAGTGTAGCAGAGGCATC, SEQ ID NO.: 12 and oBN56: AACTGCAGTTGTTTCGTATGTCATAAATTCTTTAATTAT, SEQ ID NO.: 13)

Insertion of PrM3 into MVA

In a first round, cells were infected with MVA-BN according
25 to the above described protocol and were additionally transfected with insertion vector pBN50 containing the PrM gene of Dengue virus serotype 3 and as reporter gene the *Ecogpt* gene (*Ecogpt* or shortened to *gpt* stands for phosphoribosyltransferase gene). Resulting recombinant

viruses were purified by 3 rounds of plaque purification under phosphoribosyltransferase metabolism selection by addition of mycophenolic acid, xanthin and hypoxanthin. Mycophenolic acid (MPA) inhibits inosine monophosphate dehydrogenase and results in blockage of purine synthesis and inhibition of viral replication in most cell lines. This blockage can be overcome by expressing *Ecogpt* from a constitutive promoter and providing the substrates xanthine and hypoxanthine.

10 Resulting recombinant viruses, MVA-PrM3, were identified by PCR assays using a primer pair selectively amplifying the expected insertion (oBN255 and oBN479, as described above) and as control a primer pair specifically recognizing the insertion site I4L (oBN499: CAACTCTCTTCTTGATTACC, SEQ ID

15 NO.: 14 and oBN500: CGATCAAAGTCAATCTATG; SEQ ID NO.: 15).

Coinfection of MVA-PrM1 and MVA-PrM3

The cells were infected with equal amounts of MVA-PrM1 and MVA-PrM3 according to the above protocol. After 3 rounds of plaque purification under phosphoribosyltransferase metabolism selection of blue fluorescing clones of recombinant viruses were analyzed by PCR using the primer pairs (oBN255 and oBN479. oBN499 and oBN500. oBN194 and oBN476. oBN54 and oBN56 as described above). Resulting recombinant viruses were designated MVA-PrM1/PrM3.

20

Coinfection of MVA-PrM1/PrM3 and MVA-PrM2/PrM4

25

The cells were infected with equal amounts of MVA-PrM1/PrM3 and MVA-PrM2/PrM4 according to the above protocol. Plaque purification was performed under phosphoribosyltransferase metabolism and neomycin selection. Recombinant viruses

inducing a green and blue fluorescence were isolated and analyzed by PCR using the primer pairs (oBN255 and oBN479. oBN499 and oBN500. oBN194 and oBN476. oBN54 and oBN56. oBN93 and oBN477. oBN477 and oBN452. oBN210 and oBN478. 5 oBN453 and oBN454 as described above).

The PCR analysis of the recombinant virus. (Clone 20) comprising all four PrM genes is shown in Figure 11. While in the upper part of the gel the different PCR results of the recombinant virus are shown, the lower part provides 10 the results of the same PCR reactions of the control plasmids (as indicated). Lane 1, 10 and 11 show a 1kb and a 100bp molecular marker.

The primer combination oBN210/oBN478 is specific for deletion E and PrM4 as insert. The expected PCR fragment of 15 the recombinant virus and the plasmid pBN40 has a size of 607 bp (shown in lane 2).

The primer combination oBN453/oBN454 is specific for deletion E. The expected PCR fragment of the recombinant virus is 2.7 kb, the expected band of the wild-type virus 20 2.3 kb (shown in lane 3). Also in the upper part of the gel a band specific for a wild-type virus can be identified. This means that the recombinant virus preparation is not yet completely free of wild-type virus. Further plaque purification is necessary.

25 The primer combination oBN93/oBN477 is specific for deletion A and PrM2 as insert. The expected PCR fragment of the recombinant virus and the plasmid pBN39 has a size of 636 bp (shown in lane 4).

The primer combination oBN477/oBN452 is specific for 30 deletion A. The expected PCR fragment of the recombinant

virus is 4.1 kb, the expected band of the wild-type virus 2.7 kb (shown in lane 5). In the upper part of the gel a band specific for a wild-type virus can be identified.

5 The primer combination oBN255/oBN479 is specific for intergenic region I4L and PrM3 as insert. The expected PCR fragment of the recombinant virus and the plasmid pBN50 has a size of 825 bp (shown in lane 6).

10 The primer combination oBN499/oBN500 is specific for the intergenic region of I4L. The expected PCR fragment of the recombinant virus is 1.0 kb, the expected band of the wild-type virus 0.3 kb (shown in lane 7).

15 The primer combination oBN194/oBN476 is specific for deletion 2 and PrM1 as insert. The expected PCR fragment of the recombinant virus and the plasmid pBN49 has a size of 678 bp (shown in lane 8).

20 The primer combination oBN54/oBN56 is specific for deletion 2. The expected PCR fragment of the recombinant virus is 1.6 kb, the expected band of the wild-type virus 0.9 kb (shown in lane 9). In the upper part of the gel a band specific for a wild-type virus can be identified.

Alternatively, one can produce 4 different viruses, coinfect cells with all four viruses and screen for a recombinant.

25 Improvements can also be achieved with recombination vectors, which contain further selection- or resistance markers.

Example 2**Insertion vectors**

5 *Recombination vector for intergenic region 136-137 (IGR 136-137)*

For the insertion of exogenous sequences into the MVA genome at the so-called intergenic region (IGR) 136-137
10 corresponding to the genome position 129.940 a plasmid vector was constructed which comprises about 600 bp of the flanking sequences adjacent to the insertion site. To isolate the flanking sequences from the genomic MVA-BN DNA suitable PCR primers can be designed. Such primers comprise
15 extensions with restriction enzyme sites, which will be used to clone the flanking sequences into a vector plasmid. In between this flanking sequences, a selection gene cassette is introduced, e.g. NPT II gene (neomycine resistance) under the transcriptional control of a poxviral
20 promoter (P). Additionally there is a cloning site for the insertion of additional genes or exogenous sequences to be inserted into IGR 136-137 (PacI). One such vector construct according to the present invention is disclosed in Fig. 12 (pBNX67).

25

Recombination vector for intergenic region 07-08 (IGR 07-08)

For the insertion of exogenous sequences into the MVA genome in the intergenic region (IGR) 07-08 corresponding
30 to the genome position 12.800, a plasmid vector was

constructed which comprises about 600 bp of the flanking sequences adjacent to the insertion site. To isolate the flanking sequences from the genomic MVA-BN DNA suitable PCR primers can be designed. Such primers comprise extensions with restriction enzyme sites, which will be used to clone the flanking sequences into a vector plasmid. In between this flanking sequences, a selection gene cassette is introduced, e.g., Ecogpt gene (Guanin-Phosphoribosyltransferase) under the transcriptional control of a poxviral promoter (P). Additionally, there is a cloning site for the insertion of additional genes or exogenous sequences to be inserted into IGR 07-08 (PacI). One such vector construct according to the present invention is disclosed in Fig. 13 (pBNX88).

Recombination vector for intergenic region 44-45 (IGR 44-45)

For the insertion of exogenous sequences into the MVA genome at the intergenic region (IGR) 44-45 corresponding to the genome position 37.330, a plasmid vector was constructed which comprises about 600 bp of the flanking sequences adjacent to the insertion site. To isolate the flanking sequences from the genomic MVA-BN DNA suitable PCR primers can be designed. Such primers comprise extensions with restriction enzyme sites, which will be used to clone the flanking sequences into a vector plasmid. In between this flanking sequences, a selection gene cassette is introduced, e.g., NPT II gene (neomycine resistance) under the transcriptional control of a poxviral promoter (P). Additionally there is a cloning site for the insertion of additional genes or exogenous sequences to be inserted into

IGR 44-45 (PacI). One such vector construct according to the present invention is disclosed in Fig. 14 (pBNX87).

**Construction of recombinant poxvirus comprising several
5 homologous genes integrated in its genome**

Insertion vectors

For the insertion of the three PrM genes of serotype 2, 3
10 and 4 of Dengue virus in the MVA genome, three independent recombination vectors were used.

These vectors contain - as described in detail above - sequences homologous to the MVA genome for targeting insertion by homologous recombination. Additionally each
15 vector contains a selection and reporter gene cassette.

The PrM sequences of three Dengue virus serotypes were synthetically made as described in Example 1.

As result, the insertion vector construct for IGR136-137 contained the PrM of Dengue virus serotype 4 (Fig. 15 -
20 pBN27). The insertion vector construct for IGR 07-08 contained the PrM of Dengue virus serotype 2 (Fig. 16 - pBN34), and the insertion vector construct for IGR 44-45 contained the PrM of Dengue virus serotype 3 (Fig. 17 - pBN47).

25

Generation of the recombinant MVA via homologous recombination

The generation of recombinant MVA by homologous
30 recombination was performed as described in Example 1.

The insertion sites for the PrM4, PrM3 and PrM 2 in the MVA genome are depicted in Fig. 18.

Insertion of PrM 4 into MVA

In a first round, cells were infected with MVA-BN according
5 to the above-described protocol and were additionally
transfected with the insertion vector pBN27 containing the
PrM gene of Dengue virus serotype 4 and as a reporter gene
the EGFP gene. Since the transfected vector contains a
reporter gene, EGFP, the synthesized protein is detectable
10 latest on day three in cells infected with a recombinant
virus. Resulting recombinant viruses have to be purified by
plaque purification as described in Example 1. After four
rounds of plaque purification recombinant viruses, MVA-
PrM4, were identified by PCR assays using a primer pair
15 selectively amplifying the insertion site IGR136-137
(oBN1008: gataccgatacagttcta. SEQ ID NO.: 16; and oBN1009
ggatatgattatgtagag. SEQ ID NO.: 17).

Insertion of PrM 2 into MVA

20

Cells were infected with MVA-PrM4 according to the above-
described protocol and were additionally transfected with
the insertion vector pBN34 containing the PrM gene of
Dengue virus serotype 2 and as a reporter gene the BFP
25 gene. Since the transfected vector contains a reporter
gene, BFP, the synthesized protein is detectable latest on
day three in cells infected with a recombinant virus.
Resulting recombinant viruses have to be purified by plaque
purification as described in Example 1. After six rounds of
30 plaque purification recombinant virus MVA-PrM4+PrM2 was
further passaged and amplified and a crude stock was
prepared. The recombinant was identified by PCR assays

using a primer pair selectively amplifying the insertion site IGR07-08 (oBN 903: ctggataaatacaggacgtg. SEQ ID NO.: 18; and oBN904: gacaattatccgacgcaccg; SEQ ID NO.: 19).

5 *Insertion of PrM 3 into MVA*

Cells were infected with MVA-PrM2+4 according to the above-described protocol and were additionally transfected with the insertion vector pBN47 containing the PrM gene of
10 Dengue virus serotype 3 and as a reporter gene the EGFP gene. Since the transfected vector contains a reporter gene, EGFP, the synthesized protein is detectable latest on day three in cells infected with a recombinant virus. Resulting recombinant viruses have to be purified by plaque
15 purification as described in Example 1. After three rounds of plaque purification recombinant viruses, MVA-PrM4+3+2, were identified by PCR assays using a primer pair selectively amplifying the insertion site IGR44-45 (oBN904: cgtagacaacacaccgacgatgg. SEQ ID NO.: 20; and oBN905
20 cggatgaaaaatttttgaag. SEQ ID NO.: 21).

The PCR analysis of the recombinant virus comprising the three Dengue virus PrM genes is shown in Fig. 19. PCR experiments are performed as described in Example 1. The
25 primer combination oBN1008 and oBN1009 is specific for IGR136-137, which contains the PrM4 insertion (Fig. 19, lower panel). The expected PCR fragment of the recombinant virus has a size of 1kb (shown in lane 4, 5 and 6) as the plasmid positive control (lane 8). The empty vector
30 control, devoid of PrM 4 shows the expected fragment of 190 bp (lane 2). Lane M shows the molecular weight marker and lanes 1, 3 and 7 are empty. The primer combination oBN902

and oBN903 is specific for IGR07-08, which contains the PrM2 insertion (Fig. 19, upper panel). The expected PCR fragment of the recombinant virus has a size of 960bp (shown in lane 4-6) as the plasmid positive control (lane 5 8). The empty vector control, devoid of PrM 2 shows the expected fragment of 190 bp (lane 2). The primer combination oBN904 and oBN905 is specific for IGR44-45, which contains the PrM3 insertion (Fig. 19, middle panel). The expected PCR fragment of the recombinant virus has a 10 size of 932bp (shown in lane 4-6) as the plasmid positive control (lane 8). The empty vector control, devoid of PrM 2 shows the expected fragment of 185 bp (lane 2).

⁴ Fill in if the information has been requested and if the results of the test were negative.

Certificate of Analysis

Product Description **MVA-575**
Accession Number **00120707**

Test Description: Determination of TCID₅₀ of cytopathic Virus titration. (SOP ECACC/055) Cell

Acceptance Criterion/Specification/Criteria: Negative controls should show no sign of Cytopathic effects. The Test Sample is serially diluted into in 4 wells of indicator cell lines for each dilution. Cytopathic effects indicate that virus is present. Virus titre is calculated using the below equation where x is the value obtained from a standard TCID₅₀ Table as a result of the distribution of the wells displaying less than 4 positive wells per dilution, and y is the value of the highest dilution where all 4 wells are positive:

$$TCID_{50} = \frac{1}{y} \times 10^{1+x}$$

Date:	19/01/01	
Result:	Indicator Cell Line:	BHK 21 CLONE 13
	Negative Control:	NO CPE
	Test Sample:	CPE
	Distribution of less than 4 positive wells:	4, 4, 0
	X:	0.50
	Y:	10 ⁻⁵

$$\begin{aligned}
 TCID_{50} &= \frac{1}{10^{-5}} \times 10^{1+0.50} \\
 &= 10^{6.5}
 \end{aligned}$$

Overall Result: **Virus Present**

Test Description: The Detection of Mycoplasma by Isolation on Mycoplasma Pig Serum Agar and in Mycoplasma Horse Serum Broth.
SOP QC/MYCO/01/02

Acceptance Criterion/Specification: All positive controls (*M. pneumoniae* & *M. orale*) must show evidence of mycoplasma by typical colony formation on agar plates. Broths are subcultured onto Mycoplasma Pig Serum Agar where evidence of mycoplasma by typical colony formation is evaluated. All negative control agar plates must show no evidence of microbial growth.
The criteria for a positive test result is evidence of mycoplasma by typical colony formation on agar. A negative result will show no such evidence.

Test Number:	21702	
Date:	12/02/01	
Result:	Positive Control:	Positive
	Negative Control:	Negative
	Test Result:	Negative
	Overall Result:	PASS

Authorised by.....  ECACC, Head of Quality..... *S/361* Date

Certificate of Analysis

Product Description MVA-575
Accession Number 00120707

Test Description: Detection of Mycoplasma using a Vero indicator cell line and Hoechst 33258 fluorescent detection system.
SOP QC/MYCO/07/05

Acceptance Criterion/Specification: The Vero cells in the negative control are clearly seen as fluorescing nuclei with no cytoplasmic fluorescence. Positive control (*M. orale*) must show evidence of mycoplasma as fluorescing nuclei plus extra nuclear fluorescence of mycoplasma DNA. Positive test results appear as extra nuclear fluorescence of mycoplasma DNA. Negative results show no cytoplasmic fluorescence.

Test Number: 21702

Date: 12/02/01

Result:

Positive Control:	Positive
Negative Control:	Negative
Test Result:	Negative
Overall Result:	PASS

Test Description: Detection of bacteria and fungi by isolation on Tryptone Soya Broth (TSB) and in Fluid Thioglycollate Medium (FTGM). SOP QC/BF/01/02

Acceptance Criterion/Specification: All positive controls (*Bacillus subtilis*, *Clostridium sporogenes* and *Candida albicans*) show evidence of microbial growth (turbidity) and the negative controls show no evidence of microbial growth (clear).
The criteria for a positive test is turbidity in any of the test broths. All broths should be clear for negative test result.

Test Number: 21702

Date: 12/02/01

Result:

Positive Control:	Positive
Negative Control:	Negative
Test Result:	Negative
Overall Result:	PASS

Test Number: 21487

Date: 27/11/00

Result:

Positive Control:	Positive
Negative Control:	Negative
Test Result:	Negative
Overall Result:	PASS

Test Description: Detection of Mycoplasma using a Vero indicator cell line and Hoechst 33258 fluorescent detection system.
SOP QC/MYCO/07/05

Acceptance Criterion/Specification: The Vero cells in the negative control are clearly seen as fluorescing nuclei with no cytoplasmic fluorescence. Positive control (*M. orale*) must show evidence of mycoplasma as fluorescing nuclei plus extra nuclear fluorescence of mycoplasma DNA. Positive test results appear as extra nuclear fluorescence of mycoplasma DNA. Negative results show no cytoplasmic fluorescence.

Test Number: 21487

Date: 27/11/00

Result:

Positive Control:	Positive
Negative Control:	Negative
Test Result:	Negative
Overall Result:	PASS

Certificate of Analysis

Product Description **MVA-BN**
Accession Number **00083008**

Test Description: Detection of bacteria and fungi by isolation on Tryptone Soya Broth (TSB) and in Fluid Thioglycollate Medium (FTGM). SOP QC/BF/01/02

Acceptance Criterion/Specification: All positive controls (*Bacillus subtilis*, *Clostridium sporogenes* and *Candida albicans*) show evidence of microbial growth (turbidity) and the negative controls show no evidence of microbial growth (clear).

The criteria for a positive test is turbidity in any of the test broths. All broths should be clear for negative test result.

Test Number: 21487
Date: 27/11/00
Result:

Positive Control:	Positive
Negative Control:	Negative
Test Result:	Negative
Overall Result:	PASS

Test Description: Determination of TCID₅₀ of cytopathic Virus titration. (SOP ECACC/055) Cell

Acceptance Criterion/Specification/Criteria: Negative controls should show no sign of Cytopathic effects. The Test Sample is serially diluted into in 4 wells of indicator cell lines for each dilution. Cytopathic effects indicate that virus is present. Virus titre is calculated using the below equation where x is the value obtained from a standard TCID₅₀ Table as a result of the distribution of the wells displaying less than 4 positive wells per dilution, and y is the value of the highest dilution where all 4 wells are positive:

$$TCID_{50} = \frac{1}{y} \times 10^{1-x}$$

Date: 01/12/00

Result:

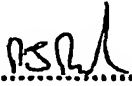

Indicator Cell Line:	BHK21 (Clone 13)
Negative Control:	NO CPE
Test Sample:	CPE
Distribution of less than 4 positive wells:	4, 4, 4, 3, 0
X:	1.25
Y:	10 ⁻³

$$TCID_{50} = \frac{1}{10^{-3}} \times 10^{1+0.25}$$

$$= 10^{4.25}$$

Overall Result: **Virus Present**
